Studies in the liverwort genus *Fossombronia* (Metzgeriales) from southern Africa. 6. New species from Lesotho, Swaziland and Mpumalanga and new records from Lesotho

S.M. PEROLD*

Keywords: *Fossombronia*, *F. angulifolia*, *F. swaziensis*, Hepaticae, Lesotho, Metzgeriales, new records, new species, southern Africa, Swaziland

**ABSTRACT**

Two new species of *Fossombronia* are described. *F. angulifolia* Perold from Lesotho and *F. swaziensis* Perold from Swaziland and Mpumalanga. *F. angulifolia* is characterised by erect or semi-erect, 2-4-lobed, angular leaves, by mostly incompletely reticulate spores and by rather short elaters. *F. swaziensis* can be recognised by large, rounded or sometimes shallowly notched leaves, which are rather stiff and bi- to multistratose basally, by quite large perigonial bracts in the male plants and by spores which have irregular areolae containing tubercular inclusions.

1. *Fossombronia angulifolia* Perold, sp. nov.

**TYPE**.—Lesotho, 2927 (Maseru): 7.5 km west of Roma along main tarred road and then south on dirt road toward Koroko, across river, on hillside above maize field, on soil between rocks. (-BC), S.M. Perold & M. Koekemoer 3711 (PRE, holo.). Same locality, S.M. Perold & M. Koekemoer 3712a (PRE, par.).

Plants smallish to medium-sized, creeping, in crowded, overlying stands, green, margins of some young leaves tinged with red, upper part of older leaves frequently dry and turning yellow, proximally becoming colourless, occasionally several small, deep pink leaves closely clasping basal part of stem; shoots mostly simple, 8.0-12.0 mm long, 1.2-1.4 mm high, ± 1.9 mm wide, rarely once furcate toward apex, sometimes with ventro-lateral innovations. *Stems* prostrate, green, in cross section (Figure 1Q), ± 310 μm (11 cell rows) high, ± 350 μm wide, basally (Figure 1R), ± 250 x 330 μm, plano-convex. *Rhizoids* purple, 15.0-17.5 μm wide. *Leaves* (Figure 1A–N) slightly overlapping to almost contiguous, erect to semi-erect (Figure 2A, B), obliquely inserted succussely, sinuose above and mostly 2-lobed, rarely 3- or 4-lobed, with shallow or deep angular lobes, dissimilar or similar in size and shape, lateral sides of leaves ± parallel or not, distally smaller, gradually enlarging proximally, (975–)1225-1450 x (500–)875-1375 μm, margins with 6–8, generally one-celled slime papillae at angulations as well as elsewhere, closer together at 'trailing' edge. *Leaf cells* (Figure 1O) thin-walled, at upper margins subquadrate to rectangular across, 20.0–25.0 x 27.5–57.5 μm, at lateral margins short- to long-rectangular, 30.0–92.5 x 12.5–27.5 μm: upper laminar cells (4–)5- or 6-sided or polygonal, 35.0–47.5 x 27.5–50.0 μm; middle laminar cells 50.0–57.5 x 30.0–40.0 μm; basal cells 50.0–62.5 x 37.5–50.0 μm. *Oil bodies* hyaline (Figure 1P), slightly granular, 9-18 per cell, round, oval or irregularly shaped, 3–6 μm diam.; chloroplasts numerous, ± 5 μm diam.

?Dicous: no male plants seen, only females. *Archegonia* dorsally scattered along stem, naked (Figure 2C), few becoming fertilised. *Pseudoperianthium* (Figure 2D–F) single, ± 1500 μm long (Figure 1U), ± 250 μm shorter than adjacent leaves, divided above into 5 irregular lobes (Figure 1V), up to 1685 μm wide across mouth, with 15 or 16 spinous processes topped by a slime papilla; cells comparable in shape and size to those of leaves, except for those in basal part, which are larger, 75.0–125.0 x 27.5–35.0 μm. *Capsule* globose, ± 600 μm diam., capsule wall bistratose, cells in inner layer irregularly shaped, variable in size, 30.0–50.0 x 25.0–32.5 μm, each cell wall with 1–3 nodular, in cross section (Figure 1T) 200 x 150 μm, 8 cells across. *Spores* light brown, hemispherical or occasionally ± oval-shaped in outline, (27.5–)32.5-45.0 μm diam., including low spines projecting around periphery (Figure 3C): distal face convex, with 10 or 11 irregular lamellae across it (Figure 3A, B), branching and anastomosing, sometimes forming areolae, 5.0–12.5 x 5.0 μm, walls slightly raised at corners, surface between lamellae finely granular (Figure 3D); proximal face (Figure 3E) mostly lacking distinct triradiate mark, with numerous very fine, irregular ridges liberally sprinkled with granules, around periphery many fine spines, shorter than 2.5 μm. *Elaters* (Figure 3F) yellow-brown, (52.5–)60.0–70.0 (90.0) μm long, often 3-spiral and uniformly up to 10 μm wide or tapering slightly toward tips, sometimes 2-spiral, 7.5–10.0 μm wide, tips 5.0 μm wide.

*Fossombronia angulifolia* is known only from the type locality in the Mountain Kingdom of Lesotho (Figure 4) which receives rain in summer and occasional snowfalls in winter. The two specimens referred to here were collected in autumn after a season of good rains. Part of the holotype specimen had to be kept in cultivation for almost two months to allow the spores in several capsules to ripen. No plants with antheridia were observed, despite thorough searching. Mosses growing together with this new species are *Bartramia hampeana* C.Müll., *Bryum canariense* Brid., *Pseudoleskeopsis* cf. *claviramea* (C.Müll.) Thér., *Gigaspernum repens* (Hook.) Lindb. as well as the liverwort, *Targionia hypophylla* L. The soil is derived from weathered sandstone and is finely to somewhat coarsely granular. The vegetation type is Afromontane Grassland (Low & Rebelo 1996). Some of the angular two-lobed

**FIGURE 2.** — *Fossombronia angulifolia*. A, arched terminal segment of thallus and leaves from side; B, shoot and leaves partly from side; C, archegonia seen from above; D, pseudoperianth (in culture stem continued growth beyond pseudoperianth); E, different shoot with pseudoperianth; F, close-up of pseudoperianth. A–F, S.M. Perold & M. Koekemoer 3711. A, × 15.7; B, × 14.2; C, E, × 19.7; D, × 11; F, × 37.6.

**FIGURE 3.** — *Fossombronia angulifolia*. Spores and elaters. A, distal face; B, side view of distal face; C, detail of areolae at margin of distal face; D, surface between lamellae on distal face; E, proximal face; F, elaters. A–F, S.M. Perold & M. Koekemoer 3711. A, × 1094; B, × 1200; C, × 2589; D, × 3533; E, × 1120; F, × 753.
leaves in *F. angulifolia* are rather similar to those found in *F. spinifolia* Steph. (Perold 1997b), but the spores in the two species differ in their ornamentation, with those in *F. spinifolia* having fewer and coarser ridges and some spiny processes in between.

2. *Fossombronia swaziensis* Perold, sp. nov.

Plantae repentes aggregatae. *Folia* superne concava vel inflexa, late patescentia, marginibus superius oblongus lateralis. *Rhizoidea* purpurea. Dioicae. *Antheridia* dorsaliter biserrata in caule, bracteis perig-nobilibus concavis 1- vel 3-lobatis obtecta. *Pseudoperianthium* plerumque supra folia reflexa eminesis; campanulatum; pedicellatum; ore subpectinato, undulato. *Sporeae* 47.5-55.0 pm diametro, superficie distali lamellis 8 vel 9 rectis vel subcurvatis, parallelis vel radiatis, irregulariter interconnexias areolas imperfectas formantis, unaquaque tuberculac 1 vel 2(3) continens; superficie proximali sine nota triradiata, cum papillulis vel spiculis humilibus, congestis, perirradiantibus, centro maioribus, circum peripheriam usque ad 21 spinulis humilibus perispore non connexis. *Elaters* 80-150 pm longi, bis vel medio ter, apices versus bis, spirales, 10-15 pm lati, plerumque apices versus contracti.

TYPE.—Swaziland, 2631 (Mhabane); Hhohho Dist., Forbes Reef, Umbuluzi River at Forbes Reef Store, on clay soil of steep streambank in wattle forest, (—AA), H.F. Glen 3130 (PRE, holo.). Same locality, H.F. Glen 3127 (PRE, para.).

Plants medium-sized to fairly large, creeping, in crowded stands; shoots with proximal parts seemingly from previous year, greyish brown, dead, or else growth interrupted by dry conditions, at apex fresh, green, mostly simple, 8-10 mm long, ± 2 mm high, 4 mm wide (up to 4.5 mm wide at pseudoperianth). *Stems* prostrate, green, occasionally peripheral cell walls in some areas of dorsal surface reddish, ventrally purple, in cross section apically ± 400 μm (10 or 11 cell rows) high, ± 700 μm wide in male plants (Figure 5N), becoming increasingly fleshy, at ± midlength, 600 μm (16 cell rows) high, 900 μm wide, tapering toward base (Figure 5O), 250 x 340 μm, plano-convex; female stems in cross section apically ± 350 x 550 μm (Figure 5P). *Rhizoids* purple, 17.5-27.5 μm wide. *Leaves* apically smaller, council to flexed above, becoming widely spreading, inserted succubously, upper and lateral margins rounded, occasionally shallowly notched, often rather stiff, basally bi- to multistratose (Figure 6C), sometimes up to ± midlength in a wide median arch (Figure 5F), proximally increasing in size, in male plants (Figure 5A–F) 1250-2000 x 1500-2125 μm, somewhat larger in female plants (Figure 5G–K), shorter than wide, 1500-2150 x 2625-3000 μm, margins at intervals with 6-8 one-celled, papilae (Figure 6B), ± 22.5 x 12.5 μm, sessile or at lower 'trailing' edge raised on (1-)2-4 basal cells. *Leaf cells* thin-walled, not appreciably different in male and female plants, at upper margins (Figure 5L) subquadrate to rectangular across, 25.0-42.5 x 50.0-82.5 μm, at lateral margins long-rectangular, 62.5-97.5 x 25.0-30.0 μm; upper laminar cells 5- or 6-sided, 40.0-57.5 x 27.5-55.0 μm; middle laminar cells 50.0-87.5 x 30.0-62.5 μm; basal cells 60.0-97.5 x 55.0-70.0 μm. *Oil bodies* disintegrated, remains executing Brownian movement on wetting; chloroplasts granular, up to 5 μm diam. (Figure 5M).

Dioicous. *Antheridia* dorsal on stem, often in 2 rows, short-stalked, ± 250 μm wide, shielded by concave perigonal bracts (Figures 5Q–S; 6D), single, 600-650 x 300-350 μm, or double, sometimes 3 lobes laterally fused together, up to 480 x 850 μm, each one topped by a papilla which is usually raised on a basal cell, marginal cells 50-75 x 45-50 μm, cells in interior 70.0-112.5 x 37.5-42.5 μm. *Archegonia* naked, in a well-spaced dorsal row. *Pseudoperianth* (Figures 5U, V, 6E, F) ± 2 mm proximal to apex, campanulate, raised on stalk up to 1000 μm long, mostly projecting above reflexed leaves, 1875-2250 μm long, 2750-2875 μm wide across mouth, sometimes partly slit along side, margin slightly scalloped, undulating, very few or no papilae seen, toward base with 2 irregularly thickened lateral outgrowths or wings; cells not appreciably different in shape and size from those in leaves. *Capsules* globose, ± 1000 μm diam., wall bistratose, cells of inner layer irregularly shaped, 30.0-37.5 x 25.0-30.0 μm, each cell wall with 1-3 dark brown nodular and some semi-annular thickenings (Figure 5T). *Seta* ± 2.5 mm long, 200 μm diam., 9 cell rows across. *Spores* light brown to darker brown, 47.5-55.0 μm diam., including lamellae projecting around periphery, hemispherical; distal face (Figure 7A–C) convex, ornamentation irregularly lamellate and incompletely reticulate, with 8 or 9 straight or slightly curved parallel or radiating lamellae, their uneven crests running across face, up to 3 μm high, 5.0-7.5 μm apart, irregularly interconnected forming mostly incomplete areolae of variable size and shape, each one containing 1 or 2 (3) tubercles (Figure 7D) with very faint ridges radiating from their bases; proximal face (Figure 7E) slightly concave, lacking triradiate mark, with low, crowded, highly irregular small papilae or spicules, becoming larger toward centre and linking up with another, around spore periphery up to 21 low 'spines', which are the 'ends' of the lamellae from the distal face extending over the sides and not connected by a perispore *Elaters* (Figure 7F) light brown, 80-150 μm long, 10-15 μm
Bothalia 28,2 (1998)

FIGURE 6.—*Fossombronia swaziensis*. A, simple stem toward apex; B, apical leaves in close-up; C, leaf base showing cell layers; D, perigonial bracts; E, pseudoperianth from side; F, pseudoperianth from above. A–C, E, F, H.F. Glen 3127; D, H.F. Glen 3130. A, × 9; B, × 29; C, × 83; D, × 19; E, × 11; F, × 10.5.

Wide in centre, mostly tapering to tips and ending in a loop, 5 μm wide, sometimes not tapering, ends blunt, ± 12.5 μm wide, bispiral or centrally trispiral and then bispiral toward ends.

*Fossombronia swaziensis* is known from the two type collections growing on clayey soil on the banks of the Umbuluzi River in a wattle forest at Forbes Reef Store (Figure 4), Hhohho District, Swaziland, with vegetation type North-Eastern Mountain Grassland (Low & Rebelo 1996), receiving >1000 mm rain annually. A third sporulating specimen was recently collected on the banks of Sterkspruit, De Kuilen, east of Lydenberg in Mpumalanga. The species can be recognised by its wide, rounded leaves, sometimes slightly inflexed above, by quite large perigonial bracts in male plants and by spores which have one to several tubercular processes in the complete or incomplete areolae. This ornamentation is

FIGURE 7.—*Fossombronia swaziensis*. Spores and elater. A, B, distal face; C, side view of distal face; D, detail of areolae on distal face; E, proximal face; F, elater. A, H.F. Glen 3127; B–F, H.F. Glen 3130. A, × 715; B, × 795; C, × 780; D, × 1400; E, × 811; F, × 681.
somewhat similar to that seen in *F. straussiana* (Perold 1997a), but there the rhizoids are hyaline, not purple as in *F. swaziensis*. The latter is also a larger plant, with entire, nonconvoluted leaves and discrete perigonial bracts subtending the antheridia. *F. swaziensis* may be far more common than the only two sporulating specimens from Forbes Reef and the single one from De Kuilen suggest, but all the other collections lack spores which are needed to confirm the determinations. This new species is also rather similar in general appearance to robust forms of *F. crispa* which, however, has reticulate spore ornamentation with the areolae lacking inclusions (Perold 1997c). The multistratose leaf bases in *F. swaziensis* may be due to the growing conditions, as Scott & Pike (1988) surmised the case to be in *F. crassifolia* Spruce, where this also occurs.

**SPECIMENS EXAMINED**

Held at PRE. Bracketed numbers after citation of collectors’ names and collecting numbers refer to the species described in the text in alphabetical order, namely: *F. angulifolia* (1) and *F. swaziensis* (2).

*Glen 3127* (2) (paratype), 3130 (2) (holotype).

*Perold & Koekemoer 3711* (1) (holotype), 3712a (1) (paratype), 4064 (2).

**NEW RECORDS OF FOSSOMBRONIA SPECIES IN LESOTHO (HELD AT PRE)**

**ACKNOWLEDGEMENTS**

I sincerely thank Dr E.O. Campbell for refereeing this article and for her helpful suggestions; Ms M. Koekemoer, curator of the National Herbarium, Pretoria, for her help with fieldwork in Lesotho and Mpumalanga as well as Dr H.F. Glen for collecting the specimens of *F. swaziensis*, for suggesting the specific epithet and for translating the diagnoses into Latin. I also extend my gratitude to Ms G. Condy for the drawings, Mrs A. Romanowski for developing and printing the photographs and to Ms D. Maree for typing the manuscript.
